Arterial occlusive arterial disease is one of the greatest challenges in the treatment of patients with end-stage renal disease. Of the various arterial access sites, the femoral vein has proven to be the best conduit for long-term hemodialysis. The first report of the autotransplantation of cephalic veins was published in the early 1980s. Although arterial transplantation is the preferred form of renal replacement therapy, patients with prior arterial grafts have been excluded from treatment with this approach. Prior vascular surgery has been associated with altered vascular reactivity, which can result in early graft thrombosis and resistance to multiple therapeutic interventions. In addition, these patients usually have multiple end-organ failures from their prior surgeries. The purpose of the present report is to review the relevant anatomy of the kidneys, the concepts of dialysis adequacy and vascular reactivity, and to demonstrate a surgical technique for revascularizing previously vascularized kidneys with veno-venous autografts. Microsoft Encrypting File System (EFS) is a feature that encrypts files or folders on Windows-based operating systems in such a manner that only the authorized user can view or access the information on the file. The only way for others to view the information is through a decryption key. This feature greatly protects and controls sensitive information, such as banking information, passwords, and personal documents. EFS implements asymmetric key cryptography to handle encryption/decryption. The first step is to encrypt the file or folder with a private key that resides on the system, which is unique to the account. Upon opening the file for reading, a synchronization process is initiated, where the file is encrypted with the client's public key. This key is copied to the client's device, which again must be unique. Now if the client wishes to access the file or folder, he can check with the system if he has the proper public key. In order to do that, the client requests the file or folder to be encrypted/decrypted with his public key. Finally, to ensure data integrity in case of loss, a verification step is initiated. The EFS data container is very small and the file size is fixed. The EFS file system uses two key sizes: the key size (i.e., 256 bits), which is the size of the public key, and the sector size (i.e., 512 bits), which is the size of the private key. The sector size must be 128 bits or smaller, so the encryption key size should not exceed 512 bits. When you create an EFS volume, the file system uses a sector size of 512 bits and a key size of
